**Keywords:** Collatz Conjecture, Divisions by Two, Binary Representation, Data Science

**Abstract.** The Collatz conjecture is an unsolved number theory problem. We approach the question by examining the divisions by two that are performed within Collatz sequences. Aside from classical mathematical methods we use techniques of data science. Based on the analysis of 10,000 sequences we show that the number of divisions by two lies within clear boundaries. Building on the results, we formulate and prove several theorems on the occurrence of cycles and the termination of Collatz sequences. The findings are useful for further investigations and could form the basis for a comprehensive proof of the conjecture.

## Introduction

### *The Problem*

The Collatz conjecture is a well-known number theory problem and is the subject of numerous publications.<sup>1</sup> Therefore, our description of the topic will be brief. The mathematician Lothar Collatz introduced a function  $g : \mathbb{N} \rightarrow \mathbb{N}$  as follows:

$$g(x) = \begin{cases} 3x + 1 & \text{if } x \equiv 1 \pmod{2} \\ x/2 & \text{if } x \equiv 0 \pmod{2} \end{cases} \quad (1)$$

The conjecture, as treated in this paper, claims that the above function leads to the final result one for every natural starting number, when applied recursively. A series of numbers involved in this process is called a Collatz sequence. With an aim to contribute to a proof of the conjecture, this paper analyses a central aspect of the problem: the divisions by two.<sup>2</sup>

### *Determining Odd Numbers*

Sultanow, Koch and Cox showed that odd numbers of Collatz sequences can be calculated with the following recursive equation<sup>3</sup>:

$$v_{n+1} = 3^n \cdot v_1 \cdot \prod_{i=1}^n \left(1 + \frac{1}{3v_i}\right) \cdot \prod_{i=1}^n 2^{-\alpha_i} \quad (2)$$

The variable  $v_1$  denotes the first odd number of the sequence, that is, the starting value. The variable  $v_i$  symbolises the odd number that is the result of a particular iteration.<sup>4</sup> The exponent  $n$  stands for the count of odd numbers that are processed by the algorithm. In the further course of this paper we will call the parameter  $n$  the *length* of a sequence. The exponent  $\alpha_i$  finally represents the number of divisions by two that is performed in a specific iteration.

---

<sup>1</sup>An overview is provided by Lagarias [1].

<sup>2</sup>Details on our scientific approach can be found in appendix "Scientific Approach".

<sup>3</sup>See Sultanow, Koch, and Cox [2, p. 10].

<sup>4</sup>For  $n = 1$  this is the starting value  $v_1$ .

Accordingly, the sum of  $\alpha_i$  is the count of divisions by two that leads from the starting value  $v_1$  to the outcome  $v_{n+1}$ . Let us consider the example  $v_1 = 13$  and  $n = 2$ . Applying equation 2 leads to:

$$v_{2+1} = 3^2 \cdot 13 \cdot \left(1 + \frac{1}{3 \cdot 13}\right) \cdot \left(1 + \frac{1}{3 \cdot 5}\right) \cdot 2^{-7} = 1$$

Starting with  $v_1 = 33$  for  $n = 3$ , we obtain the result:

$$v_{3+1} = 3^3 \cdot 33 \cdot \left(1 + \frac{1}{3 \cdot 33}\right) \cdot \left(1 + \frac{1}{3 \cdot 25}\right) \cdot \left(1 + \frac{1}{3 \cdot 19}\right) \cdot 2^{-5} = 29$$

Improving readability, we denote the factor  $\left(1 + \frac{1}{3 \cdot v_i}\right)$  with the variable  $\beta_i$  in the subsequent chapters. In addition, we generalise the formula by replacing the factor three with the variable  $k$ . This will be useful for further analysis and leads us to the following generalised version of equation 2:

$$\begin{aligned} v_{n+1} &= k^n \cdot v_1 \cdot \prod_{i=1}^n \left(1 + \frac{1}{k v_i}\right) \cdot \prod_{i=1}^n 2^{-\alpha_i} \\ v_{n+1} &= k^n \cdot v_1 \cdot \prod_{i=1}^n \beta_i \cdot \prod_{i=1}^n 2^{-\alpha_i} \end{aligned} \quad (3)$$

In order to correctly calculate odd numbers with equation 3, we must first define the halting conditions of the algorithm in the next chapter.

### ***Halting Conditions***

Being compliant with the Collatz conjecture, the algorithms 2 and 3 halt if at least one of the following conditions is fulfilled:

1.  $v_{n+1} = 1$
  2.  $v_{n+1} \in \{v_1, v_2, v_3, \dots, v_n\}$
- (4)

When the first condition applies, the Collatz conjecture is true for a specific sequence. If the second condition is fulfilled, the sequence has led to a cycle. For every starting value, except  $v_1 = 1$ , the Collatz conjecture is therefore falsified.<sup>5</sup> Let us consider the example  $k = 3$ ,  $v_1 = 13$ , and  $n = 2$ . Applying equation 3 leads to:

$$v_{2+1} = 3^2 \cdot 13 \cdot \left(1 + \frac{1}{3 \cdot 13}\right) \cdot \left(1 + \frac{1}{3 \cdot 5}\right) \cdot 2^{-7} = 1$$

In the above example the algorithm halts after two iterations because the first condition is fulfilled. If we examine the case  $v_1 = 1$ , we realise that the algorithm finishes after the first iteration, since both halting conditions are true:

$$v_{1+1} = v_1 = 3^1 \cdot 1 \cdot \left(1 + \frac{1}{3 \cdot 1}\right) \cdot 2^{-2} = 1$$

The sequence stops in the example above because the result is one. Furthermore, the sequence has led to a cycle.

---

<sup>5</sup>This statement refers to the Collatz conjecture in its original form  $3v + 1$ .

## Boundaries of $\alpha_i$

We know that in every iteration of the equations 2 and 3 at least one division by two is performed. This follows from the constraints of the Collatz problem. Consequently, we can define the minimum of  $\alpha_i$  with the following condition:

$$1 \leq \alpha_i$$

The maximum can be specified in a likewise easy way. According to the halting conditions, defined in the previous chapter, a Collatz sequence finishes when  $v_{n+1} = 1$ . The maximum of  $\alpha_i$ , hereinafter called  $\hat{\alpha}_i$ , can hence be defined as:

$$\begin{aligned} 2^{\hat{\alpha}_i} &= k \cdot v_i + 1 \\ \hat{\alpha}_i &= \log_2 k + \log_2 v_i + \log_2 \beta_i \end{aligned} \tag{5}$$

The theorem above builds on the fact that the expression  $2^{\hat{\alpha}_i}$  must equal the next even number  $k \cdot v_i + 1$  in order to lead to  $v_{n+1} = 1$ . Being greater, the result  $v_{n+1}$  would be less than one. The second step inverses the exponentiation of  $\hat{\alpha}_i$  by taking the binary logarithm. Appropriately, we replace the operation *plus one* by  $\beta_i$ . For a better understanding of the above term, let us consider the example  $k = 3$  and  $v_1 = 5$ . In this case theorem 5 results in:

$$\alpha_1 = \hat{\alpha}_1 = 4 = \log_2 3 + \log_2 5 + \log_2 \left(1 + \frac{1}{3 \cdot 5}\right)$$

If a sequence reaches the maximum  $\hat{\alpha}_i$ , it finishes with one, thus verifying the Collatz conjecture. If we could prove that every odd number finally leads to this maximum for  $k = 3$ , the Collatz problem would be solved. Summarising, we can define the following boundaries for  $\alpha_i$ :

$$1 \leq \alpha_i \leq \log_2 k + \log_2 v_i + \log_2 \beta_i \tag{6}$$

Before we continue, we validate theorem 6 empirically. We will do so at various points in this paper to avoid obvious errors in our mathematical reasoning. The basis for the validation is a sample of 10,000 Collatz sequences. The data set comprises information about sequences for the interval  $v_1 \in [1 \dots 3999]$  and  $k \in \{1, 3, 5, 7, 9\}$ . Since we do not know that all generated sequences halt, we limited the number of iterations per sequence to  $n = 100$ . For further details on the data set, see appendix "Data Set".

Unsurprisingly, we found that all values of  $\alpha_i$  in the sample are compliant with theorem 6.<sup>6</sup> In the next chapter we move on to more sophisticated considerations and study the properties of  $\prod_{i=1}^n 2^{\alpha_i}$ .

## Analysing $\alpha$

### Boundaries of $\alpha$

In equations 2 and 3, the expression  $\prod_{i=1}^n 2^{\alpha_i}$  represents the divisions by two performed by the algorithms. The number of divisions by two can be determined with the following formula and will be symbolised by  $\alpha$ :

$$\alpha = \sum_{i=1}^n 2^{\alpha_i} \tag{7}$$

---

<sup>6</sup>Source: Own empirical analysis, see appendix "Data Set" for details.

Based on theorem 6 we can define the minimum of  $\alpha$  as follows:

$$\alpha \geq n$$

Since we carry out at least one division by two in every iteration of theorem 2 and theorem 3, the minimum of  $\alpha$  equals the sequence's length. The maximum value is harder to determine. In the first step we derive it empirically from the data set mentioned in the previous chapter. Based on the observed data, we formulate the hypothesis that the maximum of  $\alpha$  can be calculated with the following equation:

$$\begin{aligned}\hat{\alpha} &= \lfloor n \cdot \log_2 k + \log_2 v_1 \rfloor + 1 \\ \alpha &\leq \hat{\alpha}\end{aligned}\tag{8}$$

The hypothesis holds for all Collatz sequences in the empirical data set.<sup>7</sup> If a Collatz sequence reaches the above formulated maximum, it finishes with one, as conjectured by Lothar Collatz. Let us, for example, consider the case  $v_1 = 13$ ,  $n = 2$  and  $k = 3$ . Applying theorems 8 and 3 leads to:

$$\begin{aligned}\hat{\alpha} &= \lfloor 2 \cdot \log_2 3 + \log_2 13 \rfloor + 1 = 7 \\ v_{2+1} &= 3^2 \cdot 13 \cdot \left(1 + \frac{1}{3 \cdot 13}\right) \cdot \left(1 + \frac{1}{3 \cdot 5}\right) \cdot 2^{-7} = 1\end{aligned}$$

Throughout the next sections we will formulate a proof of the developed hypothesis step by step.

#### ***Proving $\hat{\alpha}$ for $k = 1$***

First, we examine the case  $k = 1$ , where theorem 8 can be simplified as follows:

$$\hat{\alpha} = \lfloor n \cdot \log_2 1 + \log_2 v_1 \rfloor + 1 = \lfloor \log_2 v_1 \rfloor + 1\tag{9}$$

In order to prove theorem 8, we have to demonstrate that the number of divisions by two,  $\alpha$ , is less than or equal to the maximum  $\hat{\alpha}$ . This can be achieved by analysing the binary representation of Collatz numbers.<sup>8</sup> Let us consider the case  $v_1 = 25$  and  $k = 1$  in the decimal system. Applying theorem 3 leads to the sequence shown in the following table.

n	variable	decimal	log 2	binary	binary length	$\alpha_i$	$\alpha$	operation
1	$v_1$	25	4.64	11001 <sub>2</sub>	5			+1
	$v_1 + 1$	26	4.70	11010 <sub>2</sub>	5	1	1	$\cdot 2^{-1}$
2	$v_2$	13	3.70	1101 <sub>2</sub>	4			+1
	$v_2 + 1$	14	3.81	1110 <sub>2</sub>	4	1	2	$\cdot 2^{-1}$
3	$v_3$	7	2.81	111 <sub>2</sub>	3			+1
	$v_3 + 1$	8	3.00	1000 <sub>2</sub>	4	3	5	$\cdot 2^{-3}$
4	$v_4$	1	1.00	1 <sub>2</sub>	1			

Table 1: Binary representation of a Collatz sequence for  $k = 1$

<sup>7</sup>Source: Own empirical analysis, see appendix "Data Set" for details.

<sup>8</sup>To avoid confusion between decimal and binary numbers, we will label binary numbers with a subscripted 2.

The sequence presented in Table 1 starts with the decimal number  $v_1 = 25$  at  $n = 1$ . Subsequently it comprises the odd numbers  $v_2 = 13$ ,  $v_3 = 7$  and finally  $v_4 = 1$ . In the binary system the sequence starts accordingly with  $v_1 = 11001_2$ . The binary length of the starting number  $len(v_1)$  equals five.<sup>9</sup> This observation is crucial for our proof. For clarification, it is important to note that the length of a binary number can be calculated with the following equation<sup>10</sup>:

$$len(v_i) = \lfloor \log_2 v_i \rfloor + 1 \quad (10)$$

For example, consider the case  $v_i = 13$  in decimal, rendered in binary that means  $v_i = 1101_2$ . Here, the equation 10 leads to the following result:

$$len(13) = len(1101_2) = \lfloor \log_2 13 \rfloor + 1 = 4$$

The comparison of equation 10 with theorem 9 makes clear that they are identical. This raises the question why the maximum number of divisions by two of a Collatz sequence corresponds to the binary length of  $v_1$ .<sup>11</sup> To answer this, we take a closer look at the mechanics of a Collatz sequence in the binary system.

We start with  $v_1 = 11001_2$  in the above example. Adding one, we obtain the even number  $v_1 + 1 = 11010_2$ . The binary length of  $v_1$  equals the binary length of  $v_1 + 1$ , which is five. Due to the trailing zero we immediately realise that  $v_1 + 1$  is even. A division by two can be performed in the binary system by deleting the trailing zero. The result is  $v_2 = 1101_2$ . Adding one again, leads to the next even number  $v_2 + 1 = 1110_2$ . Deleting the trailing zero once more, results in  $v_3 = 111_2$ .

Up to this point we have performed two divisions by two. The parameter  $\alpha$  therefore equals two. The case  $v_3 = 111_2$  is very important for our proof. Adding one to  $v_3 = 111_2$ , leads to an overflow of the binary number. As a result, we obtain the even number  $v_3 + 1 = 1000_2$ , which is a power of two and equals  $2^3$  in decimal. Knowing that every power of two in a Collatz sequence directly leads to the terminal value  $v_{n+1} = 1$ , we can deduce that the sequence ends after the third iteration.

The binary length  $len(v_3) = 3$  increases to  $len(v_3 + 1) = 4$  in the final step. This situation only occurs once in a Collatz sequence for  $k = 1$ . Whenever adding one to a number  $v_n$  causes an overflow of its binary representation, the result  $v_n + 1$  will be a power of two. The binary length will in this scenario increase from  $len(v_n)$  to  $len(v_n) + 1$ . The sequence will consequently halt. For all other cases the following condition applies<sup>12</sup>:

$$len(v_n) = len(v_n + 1) > len(v_{n+1}) \quad (11)$$

Only the final iteration increases the length of the binary number. In any other case the binary length decreases from  $v_n$  to  $v_{n+1}$ .

Let us now reflect what this implies for the maximum  $\hat{\alpha}$ . We know that the binary length of the starting value  $v_1$  can be calculated with theorem 10. In order to reach the final result  $v_{n+1} = 1$ , starting at  $v_1$ , we have to perform the following number of divisions by two:

$$\alpha = \hat{\alpha} = len(v_1) + 1 - 1 = \lfloor \log_2 v_1 \rfloor + 1 \quad (12)$$

The equation builds on the binary length of the starting value  $len(v_1)$ . We add one to respect the binary overflow in the final iteration. Furthermore, we subtract the binary length of the final result  $v_{n+1} = len(v_{n+1}) = 1$ . No value of  $\alpha$  can possibly exceed this maximum, since  $\hat{\alpha}$  directly leads to the terminal value  $v_{n+1} = 1$ , halting the sequence.<sup>13</sup>

<sup>9</sup>With binary length we mean the count of the digits of a binary number.

<sup>10</sup>See Sedgewick and Wayne [3, p. 185].

<sup>11</sup>The statement is only true for  $k = 1$ .

<sup>12</sup>The statement is only true for  $k = 1$ .

<sup>13</sup>The following notebook can be used to validate the proof experimentally:

<https://github.com/c4ristian/collatz/blob/master/notebooks/binary.ipynb>

The above equation thus proves theorem 8 for  $k = 1$ . In the next chapter we will explain why this argumentation is in principle valid for all  $k$ .

### **Proving $\hat{\alpha}$ for $k > 1$**

Let us now examine the case  $k = 3$ , which is most interesting because it relates to the original Collatz conjecture. The first question we need to address is whether or not the principles discussed in the previous chapter are transferable to this form of the problem. To find an answer, we analyse a sequence, starting with  $v_1 = 17$  and  $k = 3$ . The results are displayed in the following table.

n	variable	decimal	log 2	binary	binary length	$\alpha_i$	$\alpha$	operation
1	$v_1$	17	4.09	$10001_2$	5			$\cdot 3$
	$3v_1$	51	5.67	$110011_2$	6			$+1$
	$3v_1 + 1$	52	5.70	$110100_2$	6	2	2	$\cdot 2^{-2}$
2	$v_2$	13	3.70	$1101_2$	4			$\cdot 3$
	$3v_2$	39	5.29	$100111_2$	6			$+1$
	$3v_2 + 1$	40	5.32	$101000_2$	6	3	5	$\cdot 2^{-3}$
3	$v_3$	5	2.32	$101_2$	3			$\cdot 3$
	$3v_3$	15	3.91	$1111_2$	4			$+1$
	$3v_3 + 1$	16	4.00	$10000_2$	5	4	9	$\cdot 2^{-4}$
4	$v_4$	1	1.00	$1_2$	1			

Table 2: Binary representation of a Collatz sequence for  $k = 3$

The example presented in Table 2 makes clear that in comparison to the previous case  $k = 1$ , the algorithm performs an additional operation, which is the multiplication with three. This operation leads to a growth of the binary length when comparing  $v_n$  to  $3v_n$ . The result of the operation can be calculated as follows:

$$\text{len}(3 \cdot v_n) = \lfloor \log_2 3 + \log_2 v_n \rfloor + 1 \quad (13)$$

In determining the maximum  $\hat{\alpha}$  for  $k = 3$ , we have to take the additional binary growth into account. With regard to the operation  $+1$  we can utilise the same arguments as in the previous chapter. Whenever adding one leads to an overflow in the binary representation of  $3v_n$ , the result will be a power of two, halting the sequence. The length of  $3v_{n+1}$  will, in this case, increase by one in contrast to  $3v_n$ . This can happen only once in a Collatz sequence, since the resulting power of two will lead to a termination.

In order to prove our hypothesis, we have to adjust theorem 9 by considering the additional binary growth that is caused by the multiplications with three. Therefore, we obtain the following formula:

$$\alpha = \hat{\alpha} = \lfloor n \cdot \log_2 3 + \log_2 v_1 \rfloor + 1 \quad (14)$$

The above term proves theorem 8 for the case  $k = 3$ . A closer look makes clear that it is not only valid for  $k = 3$ , but for all  $k$ . In conclusion, we can define the following boundaries for the number of divisions by two in a Collatz sequence:

$$n \leq \alpha \leq \hat{\alpha} \quad (15)$$

If one shows that every sequence finally leads to  $\hat{\alpha}$ , that means to a binary overflow of  $3v_n + 1$ , the Collatz problem would be solved. In the next chapter we will discuss the consequences of our findings for the occurrence of cycles, further confirming our line of reasoning.

## Occurence of Cycles

### Definition

A promising possibility to falsify the Collatz conjecture in its original form is a cycle. We have found such a counterexample if the following halting condition from chapter "Introduction" is fulfilled:

$$v_{n+1} \in \{v_1, v_2, v_3, \dots, v_n\}$$

The single known cycle for  $k = 3$  is the trivial one starting with  $v_1 = 1$ :

$$v_1 = 1 = v_{1+1} = 3 \cdot 1 \cdot \left(1 + \frac{1}{3 \cdot 1}\right) \cdot 2^{-2}$$

The Collatz conjecture claims that the above example is the only possibility of a cycle for  $k = 3$ . Based on theorem 3 we derive the following condition for the occurrence of a cycle within a Collatz sequence<sup>14</sup>:

$$2^\alpha = k^n \cdot \prod_{i=1}^n \beta_i \quad (16)$$

For the convenience of the reader, the expression  $\prod_{i=1}^n \beta_i$  will be referred to as  $\beta$  subsequently. Showing that theorem 16 is true for  $k = 3$ , would partially prove the Collatz conjecture. Yet there would still remain the possibility of an eternally growing sequence. This makes theorem 8 particularly interesting.

A major difficulty in analysing cycles in Collatz sequences is that there seems to be just one example. This is, however, not true for our generalised form of the problem. Let us consider the example  $k = 5$  and  $v_1 = 13$ . Applying theorem 3 leads to a cycle of the length  $n = 3$ :

$$13 = 5^3 \cdot 13 \cdot \left(1 + \frac{1}{5 \cdot 13}\right) \cdot \left(1 + \frac{1}{5 \cdot 33}\right) \cdot \left(1 + \frac{1}{5 \cdot 83}\right) \cdot 2^{-7}$$

Setting  $k = 5$  and  $v_1 = 13$  in equation 16, we obtain the following result after three iterations:

$$128 = 5^3 \cdot 13 \cdot \left(1 + \frac{1}{5 \cdot 13}\right) \cdot \left(1 + \frac{1}{5 \cdot 33}\right) \cdot \left(1 + \frac{1}{5 \cdot 83}\right) \cdot 2^{-7}$$

To determine the number of divisions by two, which can lead to a cycle, we need to investigate the parameter  $\beta$  more thoroughly.

### Analysing $\beta$

The starting point of our analysis of  $\beta$  is theorem 8. The formula can be used to calculate the maximum possible divisions by two of a Collatz sequence:

$$\hat{\alpha} = \lfloor n \cdot \log_2 v_1 \rfloor + 1$$

In chapter "Analysing  $\alpha$ " we showed that  $\hat{\alpha}$  relates to the binary length of the starting value  $v_1$ . Furthermore, the equation accounts for the binary growth, caused by the  $n$ -fold multiplication with  $k$  as well as the final overflow, triggered by the operation  $+1$ . If a sequence reaches  $\hat{\alpha}$ , it halts at the terminal value  $v_{n+1} = 1$ .

---

<sup>14</sup>See Sultanow, Koch, and Cox [2, p. 11].

In order to learn more about the parameter  $\beta$ , we take a look at the relation between theorems 8 and 3. We examine the situation in which theorem 3 leads to the final result one. Consequently, we set  $v_{n+1} = 1$  and  $\alpha = \hat{\alpha}$ :

$$\begin{aligned}
1 &= k^n \cdot v_1 \cdot \prod_{i=1}^n \beta_i \cdot 2^{-\hat{\alpha}} \\
1 &= k^n \cdot v_1 \cdot \beta \cdot 2^{-\hat{\alpha}} \\
2^{\hat{\alpha}} &= k^n \cdot v_1 \cdot \beta \\
\hat{\alpha} &= n \cdot \log_2 k + \log_2 v_1 + \log_2 \beta \\
\lfloor n \cdot \log_2 k + \log_2 v_1 \rfloor + 1 &= n \cdot \log_2 k + \log_2 v_1 + \log_2 \beta \\
\log_2 \beta &= -n \cdot \log_2 k - \log_2 v_1 + \lfloor n \cdot \log_2 k + \log_2 v_1 \rfloor + 1
\end{aligned} \tag{17}$$

For a better understanding of the above term, let us examine two examples. We begin with the border case where  $k = 1$  and  $v_1 = 1$ . Here, theorem 17 leads to:

$$\begin{aligned}
\log_2 \beta &= 1 = -n \cdot \log_2 1 - \log_2 1 + \lfloor n \cdot \log_2 1 + \log_2 1 \rfloor + 1 \\
\beta &= 2
\end{aligned}$$

Moreover, we study the example where  $k = 5$ ,  $v_1 = 19$  and  $n = 2$ . Equation 17 in this case results in:

$$\begin{aligned}
\log_2 \beta &= 0.1082 = -2 \cdot \log_2 5 - \log_2 19 + \lfloor 2 \cdot \log_2 5 + \log_2 19 \rfloor + 1 \\
\beta &= 1.0780
\end{aligned}$$

Based on theorem 17 and the fact that  $\beta$  must always be greater than one, we define the following boundaries of  $\beta$ :

$$\begin{aligned}
0 &< \log_2 \beta \leq 1 \\
1 &< \beta \leq 2
\end{aligned} \tag{18}$$

In the next chapter we will discuss the implications of theorem 18 on the occurrence of cycles.

### Analysing $\bar{\alpha}$

How many divisions by two can lead to a cycle within a Collatz sequence? We can derive an equation for this number, subsequently called  $\bar{\alpha}$ , on the basis of theorems 3 and 18. Therefore, we examine the case in which theorem 3 leads to a cycle by setting  $v_{n+1} = v_1$ :

$$\begin{aligned}
v_1 &= k^n \cdot v_1 \cdot \beta \cdot 2^{-\bar{\alpha}} \\
2^{\bar{\alpha}} &= k^n \cdot \beta \\
\bar{\alpha} &= \lfloor n \cdot \log_2 k \rfloor + 1
\end{aligned} \tag{19}$$

The last transformation above is applied, since  $\bar{\alpha}$  is a whole number. This requires us to truncate the fractional part. Knowing that  $1 < \beta \leq 2$ , we add one to the result. In a Collatz sequence a cycle can only occur, if the number of divisions by two equals  $\bar{\alpha}$ . Conversely, this does not imply that reaching  $\bar{\alpha}$  inevitably leads to a cycle. The following example demonstrates this. Let us consider the case where  $k = 3$ ,  $v_1 = 83$  and  $n = 3$ . Here, theorems 19 and 3 yield the following result:

$$\begin{aligned}
\bar{\alpha} &= 5 = \lfloor 3 \cdot \log_2 3 \rfloor + 1 \\
71 &= 3^3 \cdot 83 \cdot \left(1 + \frac{1}{3 \cdot 83}\right) \cdot \left(1 + \frac{1}{3 \cdot 125}\right) \cdot \left(1 + \frac{1}{3 \cdot 47}\right) \cdot 2^{-5}
\end{aligned}$$

Before we continue, we will empirically validate theorem 19. Our tool is a linear search performed by a Python script. For details on the program see appendix "Cycle Finder". With the script we searched

and evaluated cycles in Collatz sequences for the intervals  $v_1 \in [1 \dots 9999]$  and  $k \in [1 \dots 999]$ . In order to restrict the runtime of the program we limited the length of the investigated cycles to  $n = 100$ . The results of our empirical validation are shown in the following table 3.

$k$	$v_1 \dots v_n$	$n$	$\alpha$	$\bar{\alpha}$
1	(1)	1	1	1
3	(1)	1	2	2
5	(1, 3)	2	5	5
5	(13, 33, 83)	3	7	7
5	(27, 17, 43)	3	7	7
7	(1)	1	3	3
15	(1)	1	4	4
31	(1)	1	5	5
63	(1)	1	6	6
127	(1)	1	7	7
181	(27, 611)	2	15	15
181	(35, 99)	2	15	15
255	(1)	1	8	8
511	(1)	1	9	9

Table 3: Cycles in Collatz sequences

As one can see in Table 3, we found several cycles for our generalised form of the Collatz problem. All of them comply with theorem 19.<sup>15</sup>

### Binary Growth

As we have emphasised at several points in this paper, theorem 8 builds on the binary length of the starting value  $v_1$ . Furthermore, it accounts for the maximum binary growth, henceforth denoted with  $\hat{\Lambda}$ . We define binary growth as the total number of digits by which the binary length of  $v_1$  is increased in a sequence.<sup>16</sup> In order to calculate  $\hat{\Lambda}$ , we have to drop the starting value  $v_1$  from theorem 8:

$$\hat{\Lambda} = \lfloor n \cdot \log_2 k \rfloor + 1 \quad (20)$$

The parameter  $\hat{\Lambda}$  represents the maximum binary growth of a Collatz sequence. In other words, the binary growth of a sequence cannot exceed  $\hat{\Lambda}$ , even if we would not perform any divisions by two. Examining theorem 20, it is not surprising that we find the following relation to theorem 19:

$$\hat{\Lambda} = \bar{\alpha} = \lfloor n \cdot \log_2 k \rfloor + 1$$

As we know, a cycle occurs in a Collatz sequence, when the condition  $v_1 = v_{n+1}$  is fulfilled. The binary length of the starting number  $v_1$ , has therefore to grow exactly as much as it is reduced by the divisions by two. Thus, for a cycle to occur, the number of divisions by two has to be equal to the binary growth.

One might argue that this reasoning is erroneous, since a sequence does not necessarily reach the maximum binary growth. We build on theorem 3 to show that our arguments are valid. By setting  $v_{n+1} = v_1$ , we examine the case where the growth of the binary length of a sequence is neutralised by the divisions by two:

$$\begin{aligned} v_1 &= k^n \cdot v_1 \cdot \beta \cdot 2^{-\alpha} \\ 2^\alpha &= k^n \cdot \beta \\ \alpha &= n \cdot \log_2 k + \beta \end{aligned}$$

<sup>15</sup>Source: Own empirical analysis, see appendix "Data Set" for details.

<sup>16</sup>This means that  $\hat{\Lambda}$  does not account for the divisions by two that reduce the binary length of  $v_1$ .

Knowing that  $1 < \beta \leq 2$ , we derive the following limits for the binary growth of a Collatz sequence, subsequently called  $\Lambda$ :

$$n \cdot \log_2 k < \Lambda \leq \lfloor n \cdot \log_2 k \rfloor + 1$$

The binary growth  $\Lambda$  of every Collatz sequence must lie within these boundaries. Due to the fact that  $\bar{\alpha}$  is a whole number, it is obvious that it must equal the maximum on the right side of the expression. In any other case a cycle is impossible.

## Summary

In our paper we have shed light on a central aspect of the Collatz conjecture: the divisions by two. We analysed the problem in its original form  $3v + 1$  as well as in the generalised variant  $kv + 1$ . Based on mathematical reasoning and empirical studies we derived and proved theorems on the occurrence of cycles and the termination of sequences. Our reasoning primarily builds on the binary representation of Collatz numbers and the underlying operations. Theorem 19 determines the number of divisions by two that can lead to a cycle. The theorem is based on the simple truth that a cycle can only occur if the binary growth of a sequence is exactly neutralised by the divisions by two. Theorem 8 determines the maximum number of divisions by two that can be performed in a sequence. If one could show that every starting number finally leads to this maximum, the Collatz problem would be solved. We are convinced that a profound study of the binary mechanics of Collatz sequences will lead to this proof.

## Appendix

### Data Set

This empirical data set was used to derive and validate theorems 6 and 8. The sample was generated with a Python script and comprises information about sequences for the interval  $v_1 \in [1 \dots 3999]$  and  $k \in \{1, 3, 5, 7, 9\}$ .<sup>17</sup> Since we do not know that all generated sequences halt, we limited the number of iterations per sequence to  $n = 100$ . In total, the sample contains 651, 159 Collatz numbers, which are not necessarily distinct. This is due to the fact, that different starting numbers can lead to the same subsequent values. For example, both starting values,  $v_1 = 13$  and  $v_1 = 53$ , result in the number five.

### Cycle Finder

This Python script was used to validate theorem 19.<sup>18</sup> The program performs a linear search for the intervals  $v_1 \in [1 \dots 9999]$  and  $k \in [1 \dots 999]$ . To restrict the runtime of the script, we limited the length of the investigated cycles to  $n = 100$ . Furthermore, the results are not persisted. In order to reproduce our findings, the program must be executed again.

### Scientific Approach

The contents published in this paper have been achieved with an interdisciplinary approach. Not surprising, we applied classic mathematical theory and reasoning. Since we are convinced that the Collatz problem cannot be solved with classical maths alone, we additionally used techniques of data science. We combined the two fields in different ways. On one hand, we analysed sequences and related features empirically, in order to derive new formulas and theorems. On the other hand, we used data

science to validate our proofs. As suggested by Karl Popper, we tried to falsify them with counterexamples. In the course of our work, we have learned that the combination of the two fields leads to a very efficient working mode. This might be the topic of another paper.
